

GRID BASED NAVIGATION

Grid based navigation:-

Grid based navigation is very useful in robot's car autonomous driving, and also for path planning (in order to know the current position of vehicle and goal point (destination)).

In grid based navigation the surrounding are represented in computer memory using block of square.

- * In block of square are black then it says that we have obstacle which is at that position
- * The free space are represented by free block which color.

How to collect the data from surrounding

We will use sensor for our robot in such way that it should cover both front part & back part of robot's surrounding. So for getting both front & back part we will place sensor (or laser) at opposite direction as

Lidar-2

an assumption diagram (or)

Simple way to illustrate where to place lidar's to get over information about surrounding.

By using these data we will create a grid on our computer memory as for path planning.

How the surrounding is represented in Computer memory

Goal point

The above grid are also called as occupancy grid. where they are usually useful for representing obstacle & free surrounding of a robot's location.

* Here we can observe that if an obstacle is partially occupy the grid cell then it will be represented as fully occupied because in the occupancy grid we will use the probability algorithms like naive bayes algorithm to know the probability of obstacle.

if probability of obstacle is 1 then grid cell will be black (filled).

If probability of obstacle is 0 then grid cell will be white (empty)

If probability of obstacle is greater than 0.5 then it will be consider as that grid cell is having obstacle where robot will not move through that cell.

If probability of obstacle is less than 0.5

then we consider it as Partially placed obstacle. It is represented using a grey color where robot will move through that with an exact features.

Right now we got data of surrounding, now we need to make path planning for a moving robot car, UAV to a particular position.

How to respect represent our goal in grid cell:-

To do this we need to specify the position of goal through code as a predefined.

How to represent our goal position:-

By using LIDAR sensor or LIDAR or other devices that will emit the light ray from them and we will receive that receive the light ray and estimate the distance and position of goal (coordinates of goal).

This is a way to get the goal position if the light ray are visible to receiver sensor.

By using GPS (longitude & latitude points) if we define the position where to go then it will automatically get the position value as (Goal).

Now, we need to navigate:- From initial position to goal point.

For navigation, we need path planning. we have path, how to plan for path what which the robot car, UAV should consider.

To answer this we will use the algorithm like A*, Dijkstra's Algorithm, etc.

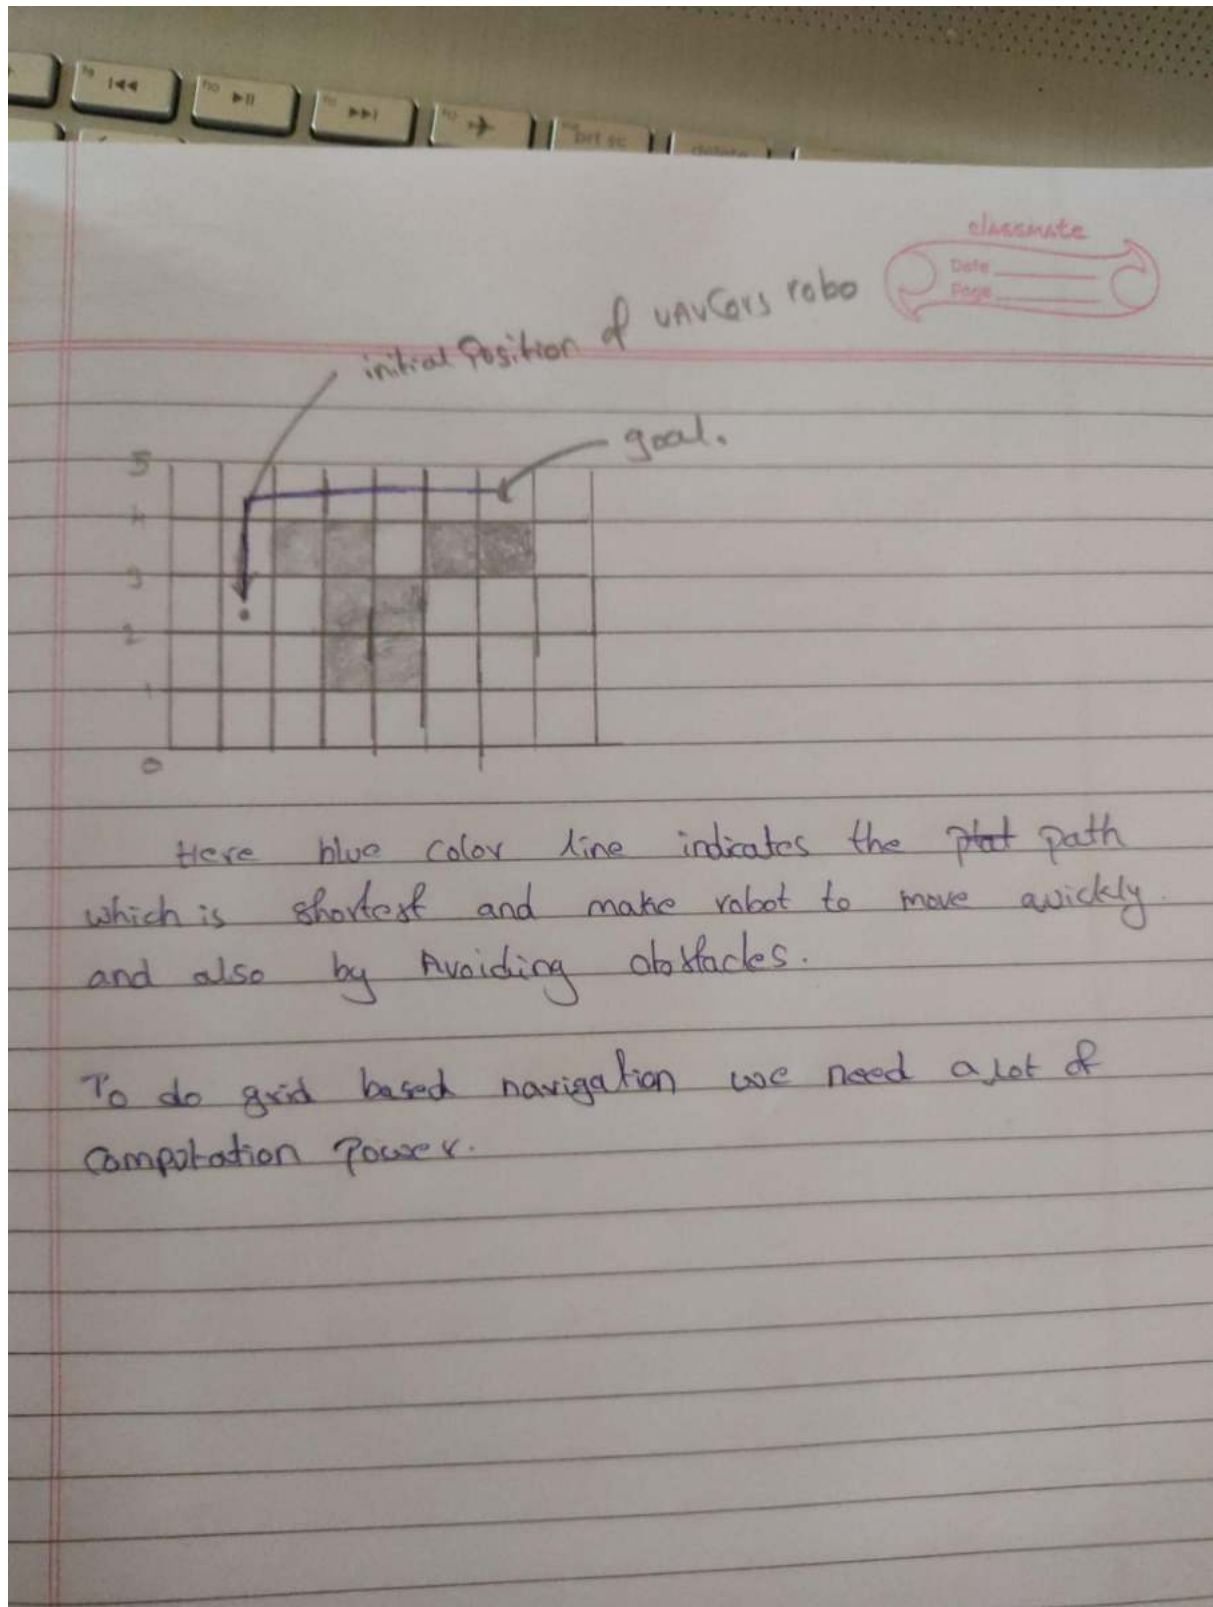

The best algorithm for deriving the shortest path in UAV navigation is often influenced by factor such as environment, mission requirement & computational resources. one widely used algorithm is Dijkstra's algorithm.

Algorithm steps

- * nodes could be waypoints, obstacles, and other significant location
- * Assign a tentative distance values to every node
Set the initial node's distance to 0 & all other to infinity.
- * we will examine neighbor's node from current node & calculate distance
- * and we will update distance if the newly calculated distance is shorter.
- * once node is explored then it is marked as visited and it will not be visited again or checked.
- * This will continue until destination node is marked as visited or all node are explored.
- * we will use Back tracking from goal node to starting node to select shortest path.

Navigation:-

After determining ~~Path planning~~ path planning we will navigate to particular goal. by ~~def~~ defining the speed of UAV (or) drone and moving it that direction according to coordinates values and also by avoiding collision with obstacles.

SIR FOR PATH PLANNING I HAVE WRITTEN A CODE AND EXECUTED

TO MAKE CHOICE OF BEST SHORTEST PATH IN GRID STARTING NODE TO GOAL
NODE

HERE IS O/P OF THE GRID BASED NAVIGATION USING A* ALGO AND DIJKSTRA ALGO

```
PS C:\Users\PAVAN SAI KUMAR\OneDrive\Desktop\hand_track> python dijkstra_maze.py maze1.txt
Maze:
